Trichomonas vaginalis is a highly successful human pathogen and the causative agent of human trichomoniasis. Trichomonas vaginalis, together with Trichomonas foetus and Monocercomonas incognita, is a member of the family Trichomonadidae, and is an anaerobic flagellated protozoan. It is found in a variety of animals and is the causative agent of trichomoniasis. The life cycle of the trichomonad has been thoroughly studied in culture, but the events in the host and the factors affecting the success of this parasite in the host are not well understood. In order to understand better the host-parasite interaction, we have recently developed a system which can be used to culture the parasite at various stages of its life cycle and to study its interaction with mammalian host cells. Using this system, we have shown that T. vaginalis invades and replicates in epithelial and endothelial cells, that this activity is due to specific activities of the parasite surface components, that the parasites adhere to epithelial and endothelial cells by attachment to heparin and fibronectin present on the cell surface, that the parasite surface components are sufficient for the adherence and that the specific attachment depends upon the nature of the host cell substrate, and that the parasite
